

Suppose we are to draw a picture of snowing in Canada. For the drawing of the snow, we can use a shared copy of snowFlakes object, since every snowFlake is completely identical. By doing so, we save our program the process of making redundant copies of objects. For the drawing of the Building however, since every Building may have different height, color etc., we will need to create a different copy for every Bulding object.

we are considering a SnowFlake as an object. because lets say all SnowFlakes are identical. we can share the same objects copy over and over again. but lets say in a City. There are a lot of Buildings not all buildings would have identical features so the copying feature won't work for buildings.
